## **Problem 1**

$$\min f1(x) = \sin(x) + 1$$

$$\min f2(x) = \cos(x) + 1$$

$$x \in [0,2\pi]$$

Utilize the Pareto ranking method for resolution and illustrate with graphs.

# SPEA2 (Strength Pareto Evolutionary Algorithm 2)

Steps:

a) Initialization: Generate an initial population  $P_t$  and create the empty archive  $\overline{P_t}$  (external set). Set t = 0.

N (population size)

 $\overline{N}$  (archive size)

T (maximum number of generations)

fitness assignment strategy

 $\overline{P}$ 

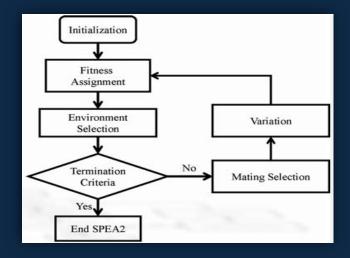

b) For each individual "i" in  $P_t$  and is assigned a strength value S(i)

$$S(i) = \frac{n}{N+1}$$

Where: "N" is the population size.

"n" is the number of individuals that are dominated by or equal to individual "i"

strength pareto: it has an important role in SPEA because this shows how solutions close to the first rank.

c) Calculates Raw fitness value based on sum of the strength of each "i" individual dominated by or equal to individual "j"

$$R(i) = \sum_{j \in P_t + \overline{P}_t, j \neq i} S(j)$$

d) To introduce variability among the solutions within the same Pareto front we calculate the density "D" corresponding to "i".

$$D(i) = \frac{1}{\sigma_i^k + 2}$$

Where:  $\sigma_i^k$  is the "k-th" nearest neighbor distance for each "i" individual.

e) Calculates Fitness value based on the sum of raw fitness + density of each individual "i".

$$F(i) = R(i) + D(i)$$

### **Environmental Selection**

f) Copy all nondominated individuals, i.e., those which have a fitness lower than "1" (Best individuals), from archive and population to the archive of the next generation:

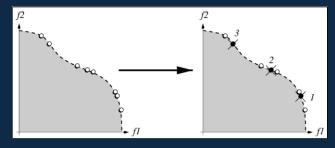

$$\overline{P}_{t+1} = \{i \mid i \in P_t + \overline{P}_t \wedge F(i) < 1\}$$

If the non-dominated front fits exactly into the archive environmental selection step is completed.

$$\left| \overline{P}_{t+1} \right| = \overline{N}$$

- h) If the archive is too small  $(|\overline{P}_{t+1}| < \overline{N})$  the best  $|\overline{N} |\overline{P}_{t+1}|$  Dominated individuals in the previous archive and population are copied to the new archive.
- i) If the archive is too large  $(|\overline{P}_{t+1}| > \overline{N})$ , an archive truncation procedure is invoked which iteratively removes individuals from  $|\overline{P}_{t+1}|$  until  $|\overline{P}_{t+1}| = \overline{N}$  that is, the individual which has the minimum distance to another individual is chosen to be eliminated.

## **Density truncation**

## NSGA-II (Non-dominated Sorting Genetic Algorithm II)

## **Fast non-dominated Sorting**

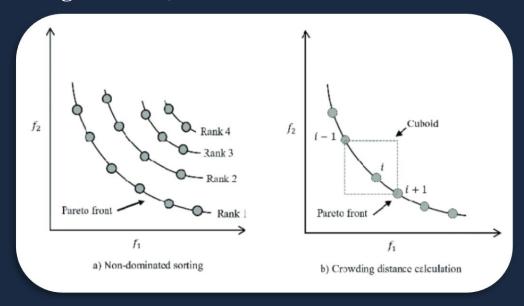

## Objective:

To divide the population into different levels of Pareto fronts based on the *concept of dominance*. solution A is said to dominate another solution B if:

- 1. A is no worse than B in all objectives, and
- 2. A is strictly better than B in at least one objective.

## Strategy:

The population is divided into different fronts. The first front (F1) contains all non-dominated solutions. The second front (F2) contains solutions that are dominated by solutions in F1 but not by each other, and so on.

## **Crowding Distance Assignment**

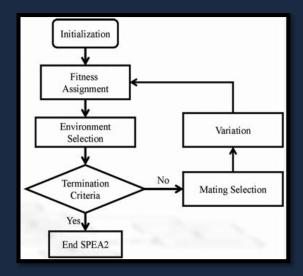

## Objective:

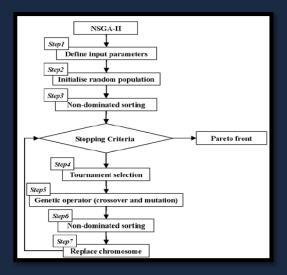

To maintain diversity among solutions within the same Pareto front.

## **Strategy:**

For each solution in a front, a crowding distance is calculated based on the Euclidean distance between adjacent solutions in the objective space.

## NSGA-II vs. SPEA2

### **Principal differences**

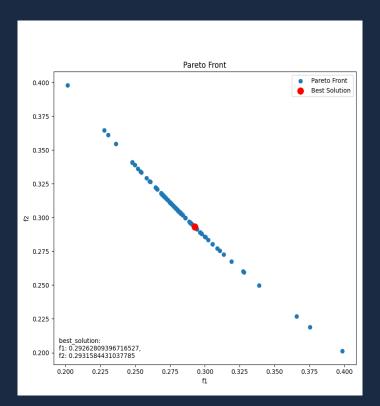

#### **Fitness Calculation:**

- In NSGA-II, fitness is based on **dominance ranking** and crowding distance.
- In SPEA2, fitness is based on strength, **raw fitness**, and **density**.

#### **Environmental Selection:**

- NSGA-II uses a selection process based on **dominance** and **crowding distance**.
- SPEA2 uses a selection process based on combined fitness and density truncation.

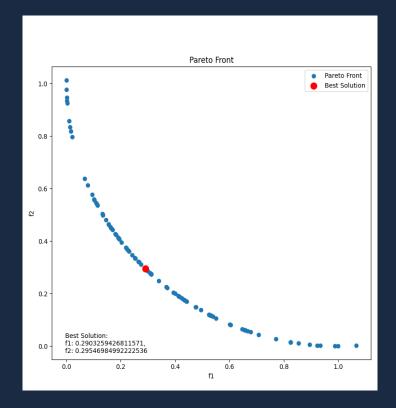

## **NSGA-II**

## **Hyperparameters:**

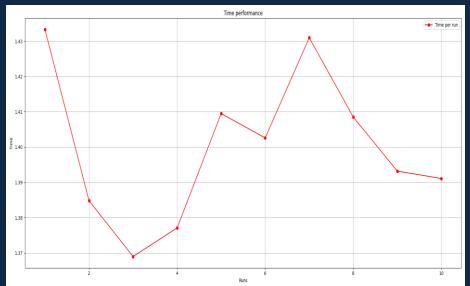

Population size = 100Generations = 100Mutation rate = 0.05

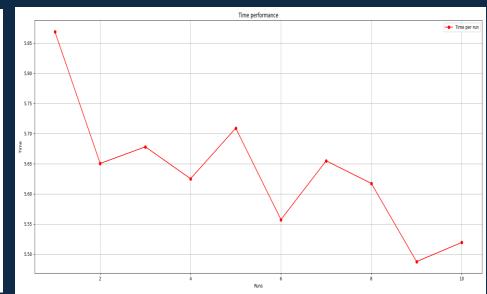

#### SPEA2

## **Experiments 10 runs**

## **Problem 2**

$$\max f 1(x1, x2) = -x1 + 3x2$$

$$\max f 2(x1, x2) = 3x1 + x2$$
s. t.  $g1(x1, x2) = x1 + 2x2 - 2 \le 0$ 

$$g2(x1, x2) = 2x1 + x2 - 2 \le 0$$

$$x1, x2 \ge 0$$

Utilize the Pareto ranking method for resolution and illustrate with graphs.

## Simple GA using special operators

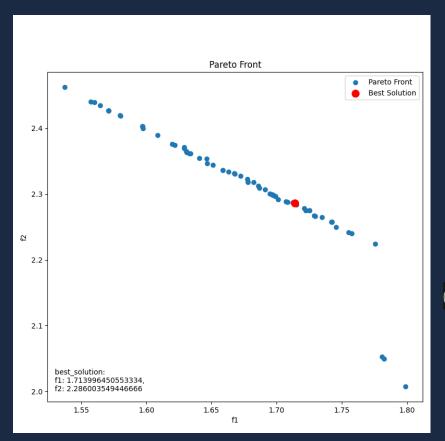

- methodology that provides a way of **handling constraints** (*linear constraints*).
- special "genetic" operators, which guarantee to keep all "chromosomes" within the constrained solution space.

## Steps:

- 1. **Initialize population :** A portion of potential solutions is selected randomly from the space of the whole feasible region; The remaining part of potential solutions consists entirely of points on the boundary of the solution space.
- **2. Selection :** Because this is a multi objective function optimization problem *Selection operator must* chose non dominated individual as best individuals.
- **3. Penalty system :** if an individual violates a constrain, it gets a penalty as a punishment, so we make sure that individual is not going to be chosen.
- 4. Crossover and mutation: should move the offspring towards the boundary of the solution space (as arithmetical crossovers, boundary mutation)
- **5. Repair system :** The main idea of the chromosome-repairing scheme is that, for an **infeasible solution**, repair it for transforming it into a **feasible solution**.

## **Experiments**

## Simple GA using special operators

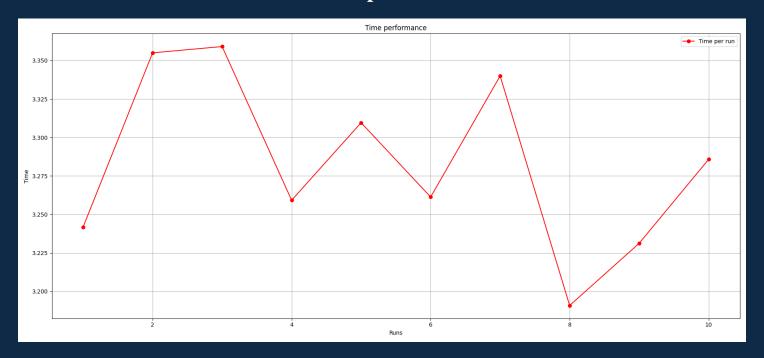

### **Hyperparameters:**

Population size = 100 Generations = 100 Mutation rate = 0.05

Generation 100: Best chromosome x1 = 0.5144, x2 = 0.7428, f1 = 1.7140, f2 = 2.2860, penalty = 0.0000

#### **Conclusions**

- For non-constrained multi objective functions problems NSGA II and SPEA 2 demonstrated to find the best solution in the pareto front ,however NSGA II due its *fast non-dominated sort system*, it surpassed the performance of SPEA 2 in run time. However further observations could be done with different kind of problems and test also the quality of the solutions, since both algorithms have a different approach for selecting the quality and diversity in the best solutions, NSGA II uses *Crowding Distance Assignment method* for maintaining the variability in the solutions by calculating the *Euclidean distance*, in the other hand SPEA 2 uses a *Density truncation method* that eliminates the solutions that are crowded in a specific area.
- A simple GA using special operators can be a fast and effective algorithm for searching the best solution for linear constrained objective functions, maintaining the individuals within the feasible area of possible solutions. However it should be tested and compared with other more complex GA algorithms.

# Thank you!
